

# Best practices for Openshift

## Importance of masters and ETCD

ETCD which is running on masters is key-value database that holds all data and objects of cluster. Any performance issues (timeouts, delays) can lead to unstable cluster.

### ETCD network considerations

Network can handle enough IO and bandwidth between masters is fast enough. Having masters in different DCs is not recommended (as rather RHACM should be used in case of OCP), but if required, network latency should be ideally below 2ms.

For Three-Node OpenShift Compact Clusters, make sure that you have dedicated NVMe or SSD drives for the control plane and separated Drives for application and another infrastructure stacks. Eventually, according to current workload in place, dedicated SSD drives for etcd (/var/lib/etcd) must be also taken in consideration.

### ETCD object count

ETCD hosted on average storage will usually have performance problems when there is more than ~8k of any of objects (like secrets, deployments, replicaset, etc..) unless you use fastest storage (with low latency and high sequential IOPS) on the market.

For excessive number of events it's not enough to delete them, but rather it should be identified which pod/operator/pipeline is producing those events.

### Namespaces

By default, there are 3 namespaces in a K8s cluster, default, kube-public and kube-system and additionally openshift-\* namespaces in OCP4.

### Pods

Don't use naked Pods (that is, Pods not bound to a ReplicaSet or Deployment) if you can avoid it.

### Readiness and Liveness Probes

Readiness and liveness probes are strongly recommended; it is almost always better to use them than to forget them. These probes are essentially health checks.

Readiness probe ensures a given pod is up-and-running before allowing the load to get directed to that pod. If the pod is not ready, the requests are taken away

from your service until the probe verifies the pod is up. Liveness probe verifies if the application is still running or not. This probe tries to ping the pod for a response from it and then check its health. If there is no response, then the application is not running on the pod. The liveness probe launches a new pod and starts the application on it if the check fails.

## Resource Requests and Limits

Resource limits are the operating parameters that you provide to kubernetes that tell it two critical things about your workload: what resources it requires to run properly; and the maximum resources it is allowed to consume. The first is a critical input to the scheduler that enables it to choose the right node on which to run the pod. The second is important to the kubelet, the daemon on each node that is responsible for pod health.

```
resources:
  requests:
    cpu: 50m
    memory: 50Mi
  limits:
    cpu: 100m
    memory: 100Mi
```

Resource requests specify the minimum amount of resources a container can use  
Resource limits specify the maximum amount of resources a container can use.

## Deployments and Replicasets

.spec.revisionHistoryLimit is an optional field that specifies the number of old ReplicaSets to retain to allow rollback. These old ReplicaSets consume resources in etcd and crowd the output of kubectl get rs. The configuration of each Deployment revision is stored in its ReplicaSets; therefore, once an old ReplicaSet is deleted, you lose the ability to rollback to that revision of Deployment. By default, 10 old ReplicaSets will be kept, however its ideal value depends on the frequency and stability of new Deployments.

This means, that with 2000 deployments you could create up to 20k replicasets and this could have huge performance impact on ETCD.

## Operators

TODO

### What is Operator doing?

Main concern should be what is operator doing and what overhead it brings. Operators that do lot of API calling, ones that scan the files or create heavy IO/traffic could have big performance impact on the storage. Make sure you

understand what Operator is doing, how it affects overall performance and how you can tweak it to avoid such issues.

### **Where does Operator run?**

If Operator runs also on masters (virus or file scanner), it could have performance impact on storage (and therefor impact on ETCD).

### **Does Operator call OCP API?**

TODO

### **Does Operator create CRDs?**

TODO

## **Pipelines**

Pipeline can be simple, but also complex commands that could create high IO or API activity.

## **3rd party software and services**

TODO

## **Logging**

Customer applications produce logs and you should consider add enough resources (CPU/RAM) to monitoring/infra nodes.

## **When to use a ReplicaSet**

A ReplicaSet ensures that a specified number of pod replicas are running at any given time. However, a Deployment is a higher-level concept that manages ReplicaSets and provides declarative updates to Pods along with a lot of other useful features. Therefore, we recommend using Deployments instead of directly using ReplicaSets, unless you require custom update orchestration or don't require updates at all.

This actually means that you may never need to manipulate ReplicaSet objects use a Deployment instead, and define your application in the spec section.

## **CLEANUP**

It is very important to clean up unused resources that could be referencing other unneeded resources like images or secrets. If you run any pipeline that creates CRDs, make sure there is pipeline also to clean up those CRDs.
